ORIcontrol PLUS

Orius again in the limelight

A paradigm shift in the biological control of thrips.

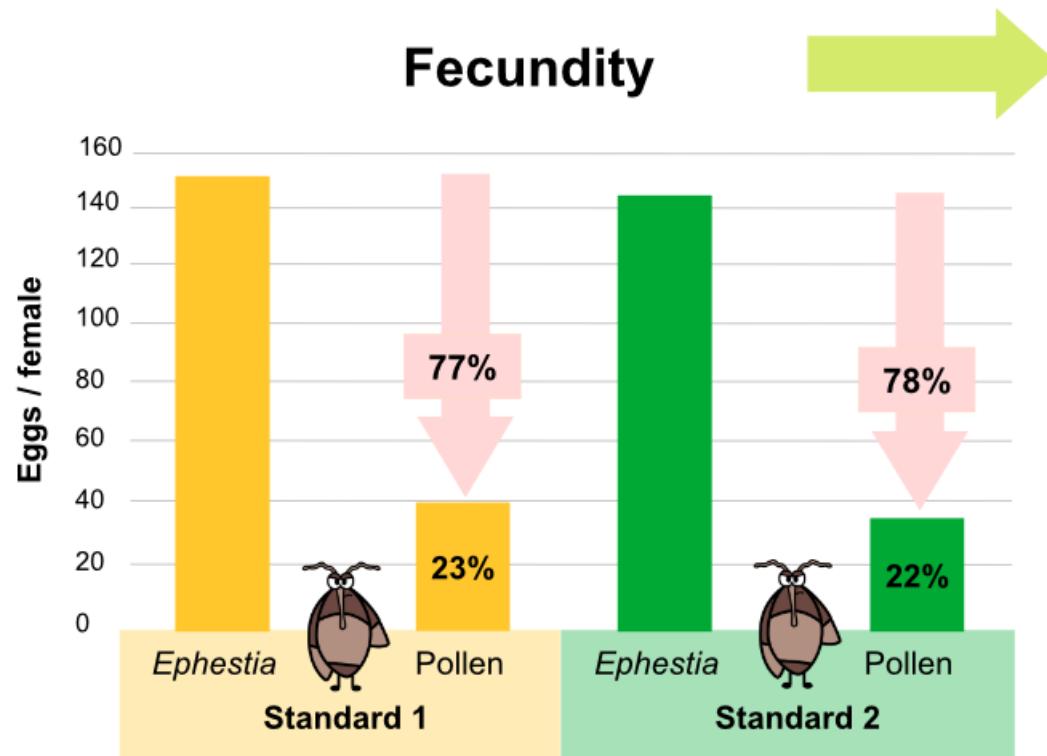

Enric Vila, Agrobio S.L. & Pablo Bielza, UPCT

**Agrobio**

Universidad
Politécnica
de Cartagena

Persistence of predators relies on feeding on pollen... but fitness significantly drops (suboptimal food)

Inferior numerical response
Slow reproduction and establishment

ORIcontrol PLUS

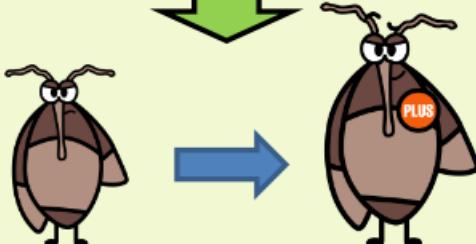

Strain better adapted to feeding on pollen

>30 wild populations of
Orius laevigatus

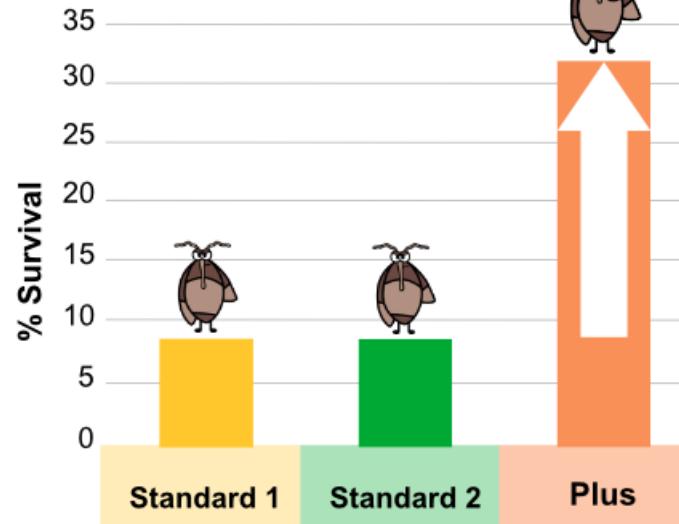

After 10 years of classical
genetic selection

Enhanced fitness when
feeding on pollen

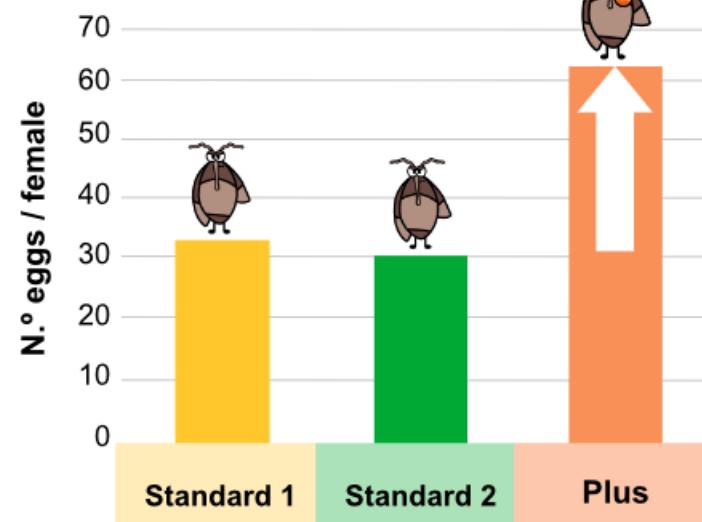

Immature survival

x3.5 more survival

Fecundity

32 eggs more

Prey mites in-crop food

- *T. montdorensis*
with Powerfood
- *A. swirskii*
with Powermite

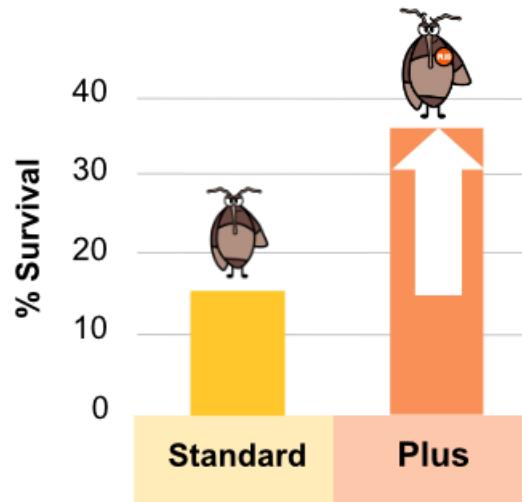

ORIcontrol PLUS

**Surprisingly also better performance feeding
other suboptimal food (prey mites)**

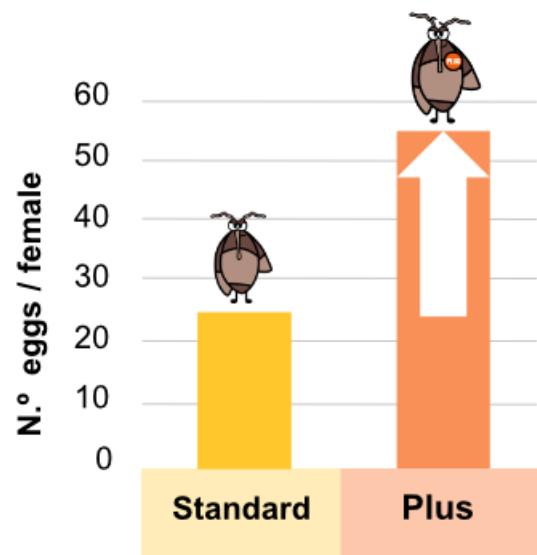

**Significant increase of
fitness when feeding
on prey mites**

Immature survival

Fecundity

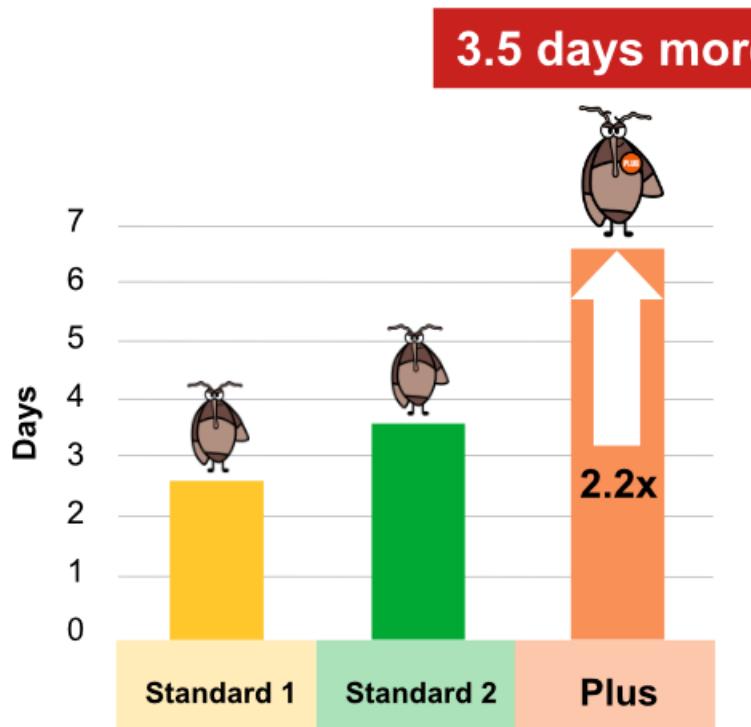

Any trade-offs?

What happens if they do not find any food?

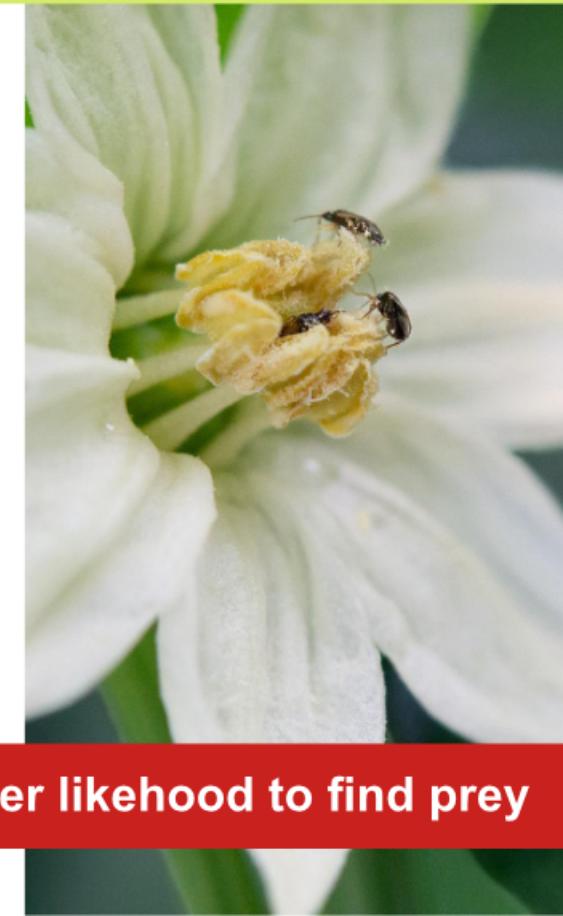

Longevity under starvation

Enhanced RESILIENCE

Higher capacity to
overcome critical
periods

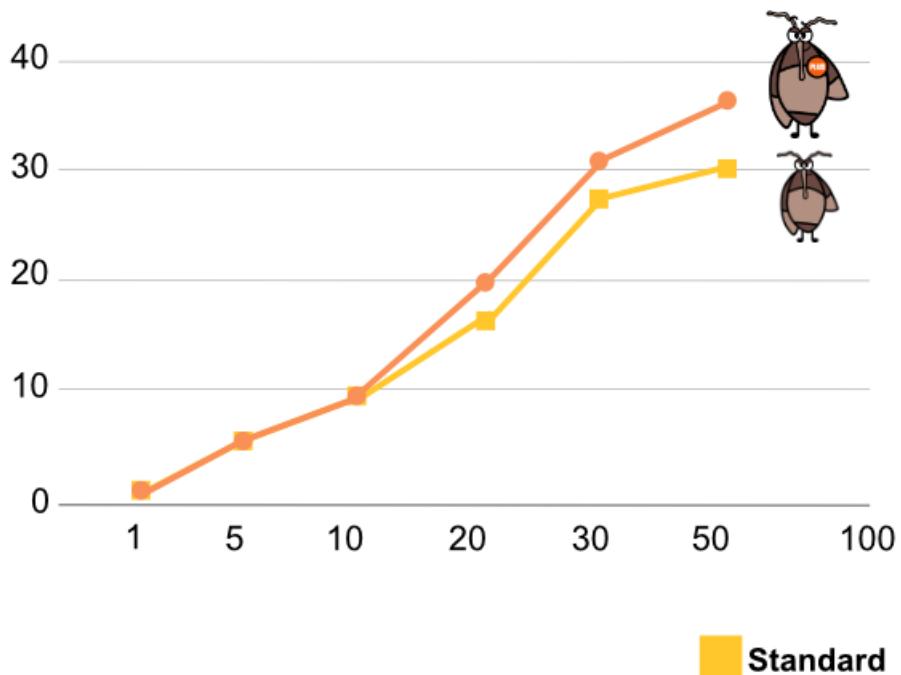

Survival increase → higher likelihood to find prey

Any trade-offs?

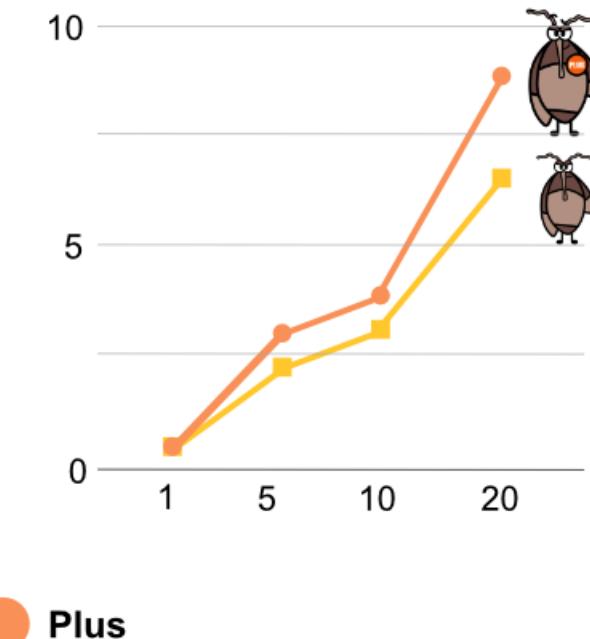

If better adapted to plant food, what about predation?

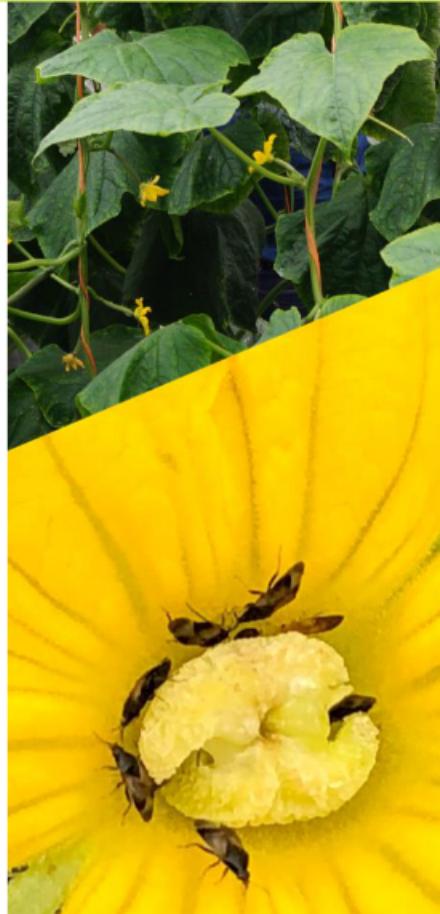

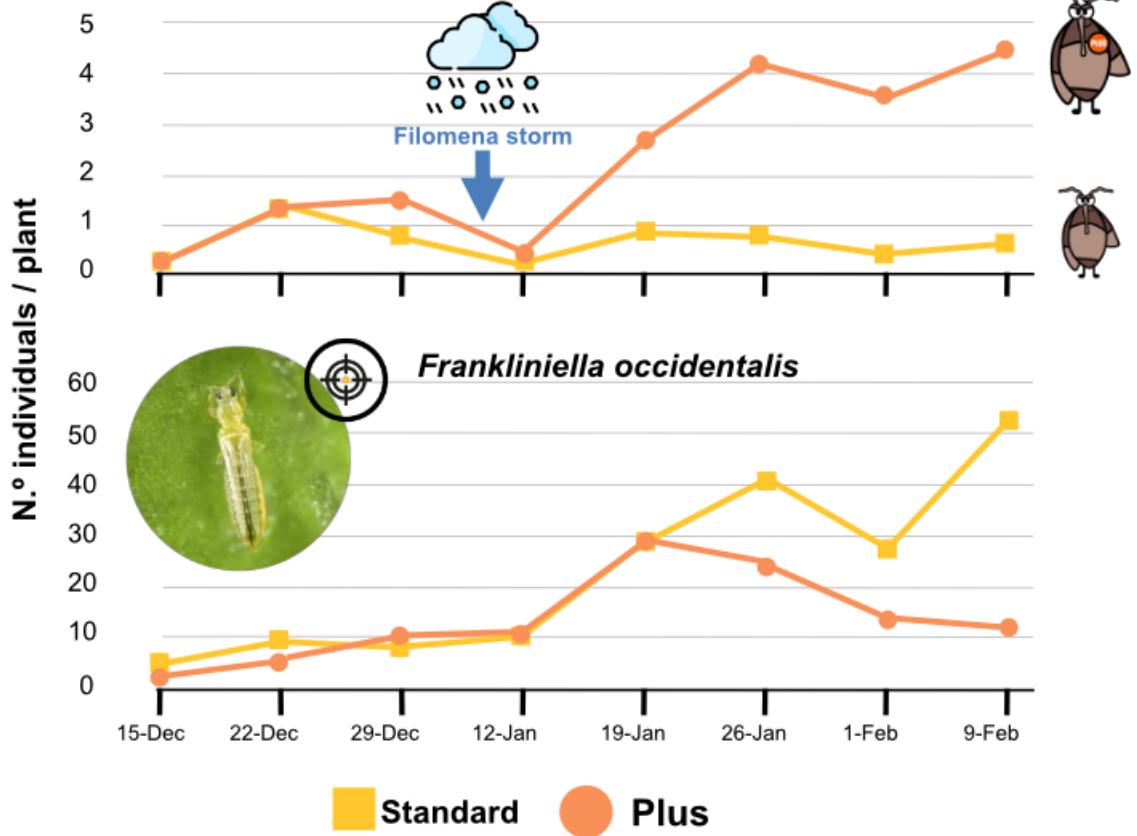

Predation rate on thrips larvae

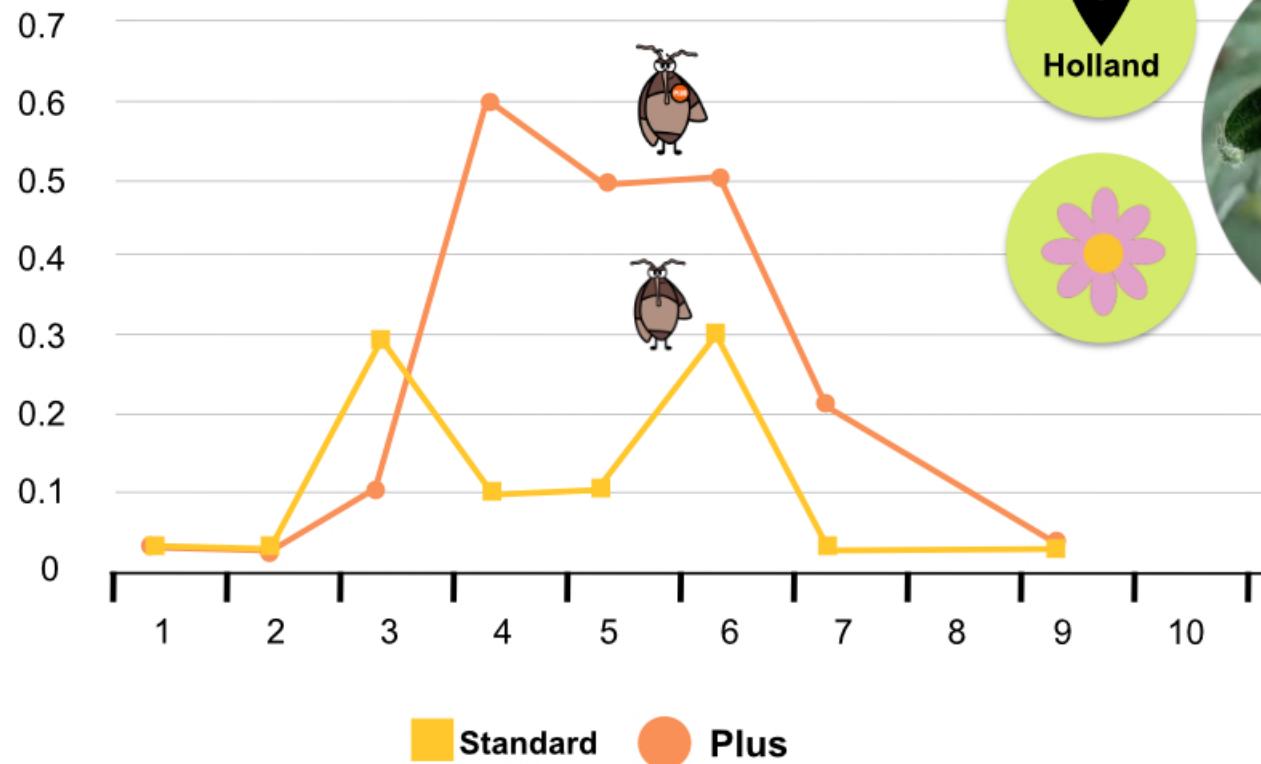

Predation rate on thrips adults

Field performance on plants without pollen

Field performance on plants without pollen

Take-home messages

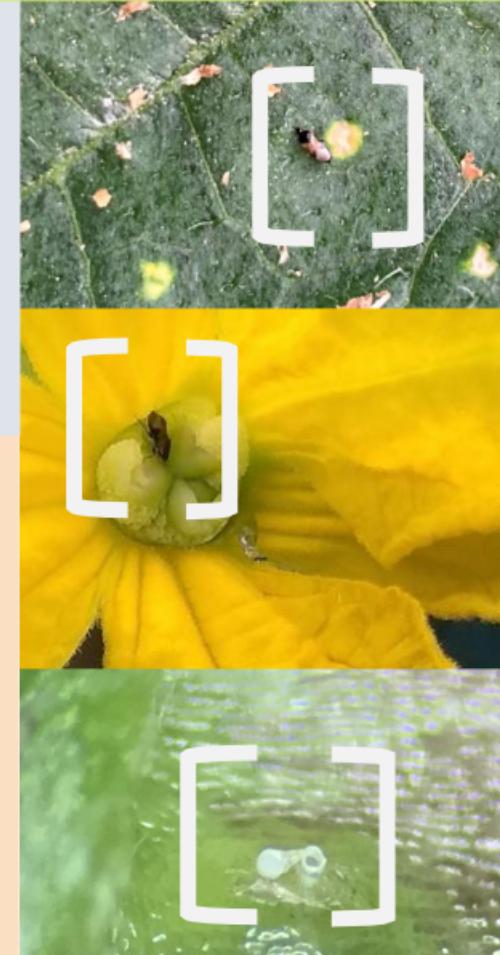

**NEW,
Unique &
Scientific value**

- First genetic selection of IBCA giving a successful commercial product.
- It improves the control of thrips.
- A robust & more resilient preventive strategy can be settled.

**MARKET
placement &
Coming uptake
of biocontrol**

Preventively used with an affordable in-crop feeding strategy in:

- vegetable crops without pollen (cucumbers, seedless pepper varieties...)
- ornamental crops without flowers (chrysanthemums, roses, pot plants...)
- open field crops (onions, orchards...).

Many thanks for your attention!
